Using the Cre-deletor strain Hoxb7-Cre, Washington University researchers developed transgenic mice with loxP sites flanking the gene for the glial cell line-derived neurotrophic factor (GDNF) family receptor  $\alpha 1$  (GFR $\alpha 1$ ), which is involved in kidney tissue development. These mice were then used to determine the role of GFR $\alpha 1$  in the development of different cell types and in different stages of development.

**Publication:** [Stage specific requirement of Gfr \$\alpha 1\$  in the ureteric epithelium during kidney development](#)
